

# INFINITY CATEGORIES

LECTURER: PRAMOD ACHAR, TYPESETTER: MICHAŁ MRUGAŁA

## §1. SIMPLICIAL SETS

**Definition.** — The **simplex category**  $\Delta$  is the category of

- finite non-empty totally ordered sets
- order-preserving maps.

**Notation.** —  $[n] = \{0 < 1 < 2 < \dots < n\}$  for  $n \in \mathbb{Z}_{\geq 0}$ .

Every object in  $\Delta$  is (uniquely) isomorphic to some  $[n]$ .

**Definition.** — A **simplicial set** is a functor

$$\mathcal{S} : \Delta^{\text{op}} \longrightarrow \text{Sets}$$

**Notation.** —  $\mathcal{S}_n := \mathcal{S}([n])$ , call this the **set of  $n$ -simplices** of  $\mathcal{S}$ . 0-simplices are called **vertices**, 1-simplices are called **edges**.

**Example 1.0.1.** — Let  $C$  be a set. Let  $\underline{C} : \Delta^{\text{op}} \rightarrow \text{Sets}$  be the constant functor:

$$\begin{aligned} \underline{C}_n &= C \quad \forall n, \\ \underline{C}(\alpha) &= \text{id} \quad \forall \alpha : [m] \longrightarrow [n] \text{ in } \Delta. \end{aligned}$$

This is called a **discrete simplicial set**.

**Definition.** — Let  $\mathcal{S}$  be a simplicial set. Given  $\alpha : [n] \rightarrow [n-1]$  we get  $\mathcal{S}(\alpha) : \mathcal{S}_{n-1} \rightarrow \mathcal{S}_n$ . The  $n$ -simplices in the image are called **degenerate** simplices, i.e.  $\sigma$  is degenerate if there is an  $\alpha$  such that  $\sigma \in \text{im}(\mathcal{S}(\alpha))$ .

**Lemma 1.0.1.** — A simplicial set is discrete if and only if for all  $n \geq 1$  all  $n$ -simplices are degenerate.

**Exercise.** — Prove it.

**Example 1.0.2.** — Let  $(P, \geq)$  be a poset. Define a simplicial set  $N(P, \leq)$  called the **nerve** of  $(P, \leq)$  by

$$N(P, \leq)_k = \{\text{chains } p_0 \leq p_1 \leq \dots \leq p_k : p_i \in P\}$$

where a chain is a totally ordered subset.

**Exercise.** — Finish the definition. Which simplices are degenerate?

**Example 1.0.3 (“Standard  $n$ -simplex”).** — The **standard  $n$ -simplex** is

$$\Delta^n := N([n]).$$

(Pictures)

**Note.** — For  $j \in [n]$ , we get a subsimplicial set

$$N([n] \setminus \{j\}) \subset \Delta^n$$

isomorphic to  $\Delta^{n-1}$  called the  $j^{\text{th}}$  **face** of  $\Delta^n$ . (Picture)

**Example 1.0.4 (Horns).** — Let  $n \geq 0$  and  $0 \leq j \leq n$ , define the **horn**

$$\begin{aligned} \Lambda_j^n &:= \begin{aligned} &\text{subsimplicial set of } \Delta^n = N([n]) \\ &\text{consisting of chains } p_0 \leq p_1 \leq \dots \leq p_k \text{ (Pictures)} \\ &\text{such that } \{p_0, \dots, p_k\} \not\supset [n] \setminus \{j\}. \end{aligned} \end{aligned}$$

**Example 1.0.5 (( $n - 1$ )-sphere  $\partial\Delta^n$ ).** — We define the  $(n - 1)$ -**sphere**

$$\partial\Delta^n := \begin{array}{c} \text{subsimplicial set of } \Delta^n \\ \text{chains } p_0 \leq \cdots \leq p_k \text{ such that } \{p_0 \leq \cdots \leq p_k\} \neq [n] \end{array}$$

**Example 1.0.6 (Products).** — Let  $\mathcal{S}, \mathcal{T}$  be simplicial sets. We define their **product**  $\mathcal{S} \times \mathcal{T}$  as

$$(\mathcal{S} \times \mathcal{T})_k = \mathcal{S}_k \times \mathcal{T}_k.$$

(Picture)

**Example 1.0.7.** — Let  $\mathbf{C}$  be an ordinary category. We define its **nerve**  $N(\mathbf{C})$  as

$$N(\mathbf{C})_k := \left\{ \begin{array}{c} \text{composable sequences of morphisms} \\ X_0 \xrightarrow{f_1} X_1 \xrightarrow{f_2} X_2 \rightarrow \cdots \xrightarrow{f_k} X_k \end{array} \right\}.$$

**Example 1.0.8.** — Let  $X$  be a topological space. The **singular simplicial set** of  $X$  is defined as

$$\text{Sing}(X)_k = \{\text{continuous maps } |\Delta^k| \rightarrow X\},$$

where  $|\Delta^k|$  is the standard  $k$ -simplex

$$|\Delta^k| = \left\{ (x_0, \dots, x_k) \in \mathbf{R}^{k+1} \mid x_i \geq 0, \sum x_i = 1 \right\}.$$

**Exercise.** — What does this do to the morphisms in  $\Delta$ ?

**Definition.** — A **Kan complex** is a simplicial set  $X$  such that for every diagram

$$\begin{array}{ccc} \Delta_j^n & \xrightarrow{\text{any map}} & X \\ \downarrow & \nearrow \text{dashed} & \\ \Delta^n & & \end{array}$$

we can fill the dashed arrow. This is called an **extension problem**. If the arrow exists we say that the extension problem **admits a solution**.

Daniel Kan discovered Kan complexes in 1958. The *key fact* is that  $\text{Sing}(X)$  is a Kan complex. The theme from 1958 to today is that Kan complexes are a “combinatorial model” for algebraic topology which allows us to do homotopy theory.

**Definition.** — Let  $X$  be a Kan complex and  $\mathcal{S}$  be any simplicial set. Two maps  $f, g : \mathcal{S} \rightarrow X$  are said to be **homotopic** if there exists a map  $H : \mathcal{S} \times \Delta^1 \rightarrow X$  such that

$$H|_{\mathcal{S} \times \{0\}} = f, \quad H|_{\mathcal{S} \times \{1\}} = g.$$

**Lemma 1.0.2.** — *This is an equivalence relation.*

*Proof.* Omitted, tricky for an exercise. This requires  $X$  to be a Kan complex. □

**Definition.** — Let  $X$  be a Kan complex and  $x_0$  be a vertex of  $X$ . Let

$$\text{Loops}_{x_0} = \{\text{maps } \gamma : \Delta^n \rightarrow X \text{ such that } \gamma|_{\partial\Delta^n} \text{ is the constant map to } x_0\}.$$

We say  $\gamma, \gamma' \in \text{Loops}_{x_0}$  are **relatively homotopic (rel. homotopic)** if there exists  $H : \Delta^n \times \Delta^1 \rightarrow X$  such that

$$H|_{\Delta^n \times \{0\}} = \gamma, \quad H|_{\Delta^n \times \{1\}} = \gamma', \quad H|_{\partial\Delta^n \times \Delta^1} = \text{const. map to } x_0.$$

Define

$$\pi_n(X, x_0) := \frac{\text{Loops}_{x_0}}{\text{rel. homotopy}}.$$

**Fact.** — For  $n \geq 1$ ,  $\pi_n(X, x_0)$  is a group. For  $n \geq 2$ ,  $\pi_n(X, x_0)$  is abelian.

**Definition.** — An  $\infty$ -category (or **quasi-category**) is a simplicial set  $\mathcal{C}$  such that any extension problem

$$\begin{array}{ccc} \Lambda_j^n & \longrightarrow & \mathcal{C} \\ \downarrow & \nearrow & \\ \Delta^n & & \end{array}$$

with  $0 < j < n$  (**inner horns**) admits a solution. (Picture) An  $\infty$ -category is also called a **weak Kan complex**.

**Lemma 1.0.3.** — Let  $C$  be an ordinary category, then  $N(C)$  is an  $\infty$ -category.

*Digression:* Let  $I^n$  be the simplicial set consisting of  $n$  consecutive 1-simplices ( $n$ -**spine**) (Picture). A naive alternative definition is:  $\mathcal{C}$  is an infinity category if every

$$\begin{array}{ccc} I^n & \longrightarrow & \mathcal{C} \\ \downarrow & \nearrow & \\ \Delta^n & & \end{array}$$

has a solution. This is WRONG (but its wrongness is subtle), even though  $N(\text{ord. cat.})$  satisfy this. There is a book by Markus Land “Introduction to  $\infty$ -categories” which explores this. The definition of  $\infty$ -categories was introduced by Boardman-Vogt in 1972. Joyal started generalizing results from ordinary category theory to  $\infty$ -categories in 2006. Lurie is largely responsible for how well this notion is developed in modern literature.

**Remark.** — Having a unique solution to the lifting problem characterizes nerves of ordinary categories.

**Definition.** — Let  $\mathcal{C}$  be an  $\infty$ -category. An **object** is a vertex. A **morphism** is an edge. An **identity morphism** is a degenerate edge. Say that  $h$  is a **composition** of  $g$  and  $f$  if there exists a 2-simplex such that (Picture).

**Remark.** — Compositions are NOT unique in  $\infty$ -categories.

**Example 1.0.9 ( $\infty$ -categories).** —

1) Topological spaces  $\text{Top}$ .

- Objects are topological spaces.
- Morphisms are continuous maps.
- A 2-simplex is a (not necessarily commutative) diagram

$$\begin{array}{ccc} & X_1 & \\ f \nearrow & & \searrow g \\ X_0 & \xrightarrow{h} & X_2 \end{array}$$

and a homotopy  $H : X_0 \times [0, 1] \rightarrow X_2$  from  $gf$  to  $h$ .

- A 3-simplex is a diagram

$$\begin{array}{ccccc} & & X_0 & & \\ & \swarrow & \downarrow & \searrow & \\ X_1 & & & & X_3 \\ & \searrow & \downarrow & \swarrow & \\ & & X_2 & & \end{array}$$

with continuous maps  $f_{ij} : X_i \rightarrow X_j$  for  $i < j$ , homotopies  $T_{ijk} : X_i \times [0, 1] \rightarrow X_k$  from  $f_{jk} \circ f_{ij}$  to  $f_{ik}$ , and  $H : X_0 \times [0, 1]^2 \rightarrow X_3$  (**higher homotopy**) such that  $H|_{\text{bdry}}$  is

$$\begin{array}{ccc} (0,0) & \xrightarrow{T_{123}f_{01}} & (0,1) \\ f_{23}T_{012} \downarrow & & \downarrow T_{013} \\ (1,0) & \xrightarrow{T_{023}} & (1,0) \end{array}$$

2) The  $\infty$ -category of ordinary categories  $\text{Cat}_1$ .

- Objects are ordinary categories.
- Morphisms are functors.
- A 2-simplex is a (not necessarily commutative) diagram

$$\begin{array}{ccc} & X_1 & \\ f \nearrow & & \searrow g \\ X_0 & \xrightarrow{h} & X_2 \end{array}$$

and a natural isomorphism  $T : g \circ f \xrightarrow{\sim} h$ .

- A 3-simplex is a diagram

$$\begin{array}{ccccc} & & X_0 & & \\ & \swarrow & & \searrow & \\ X_1 & & & & X_3 \\ & \searrow & & \swarrow & \\ & & X_2 & & \end{array}$$

where  $f_{ij}$  are functors and  $T_{ijk}$  are natural isomorphism such that

$$\begin{array}{ccc} \bullet & \xrightarrow{T_{123}f_{01}} & \bullet \\ f_{23}T_{012} \downarrow & & \downarrow T_{013} \\ \bullet & \xrightarrow{T_{023}} & \bullet \end{array}$$

commutes

A source of  $\infty$ -categories are

- ordinary categories with an equivalence relation on morphisms,
- ordinary categories with inverting some morphisms.

Lecture 2

**Definition.** —

1. Let  $C$  be an  $\infty$ -category and  $f : X \rightarrow Y$  be a morphism in  $C$ .  $f$  is called an **isomorphism** if there exists  $g : Y \rightarrow X$  and two 2-simplices

$$\begin{array}{ccc} & Y & \\ f \nearrow & & \searrow g \\ X & \xrightarrow{\text{id}_X} & X \end{array} \quad \begin{array}{ccc} & X & \\ g \nearrow & & \searrow f \\ Y & \xrightarrow{\text{id}_Y} & Y \end{array}$$

2. An  $\infty$ -category is called an  **$\infty$ -groupoid** if every morphism is an isomorphism.

**Theorem 1.0.1 (Joyal).** — *An  $\infty$ -category is an  $\infty$ -groupoid if and only if it is a Kan complex.*

*Proof.* The forward direction is hard, the converse is an exercise. □

**Definition.** —

3. Say  $f, g : C \rightarrow D$  are functors (morphisms of simplicial sets) of  $\infty$ -categories. A **natural transformation** from  $f$  to  $g$  is a functor  $T : C \times \Delta^1 \rightarrow D$  such that  $T|_{C \times \{0\}} = f$  and  $T|_{C \times \{1\}} = g$ .

A special case: the identity natural transformation  $\text{id}_f : f \rightarrow f$  is the map

$$C \times \Delta^1 \xrightarrow{\text{proj}} C \xrightarrow{f} D.$$

$T : f \rightarrow g$  is a **natural isomorphism** if there exists  $T' : g \rightarrow f$  and two maps  $H : C \times \Delta^2 \rightarrow D, H' : C \times \Delta^2 \rightarrow D$  such that

$$\begin{array}{ccc} & g & \\ T \nearrow & & \searrow T' \\ f & \xrightarrow{\text{id}_f} & f \end{array} \quad \begin{array}{ccc} & f & \\ T' \nearrow & & \searrow T \\ g & \xrightarrow{\text{id}_g} & g \end{array}$$

In ordinary category theory a natural transformation assigns objects in  $C$  to morphisms in  $D$  and morphisms in  $C$  to commutative squares in  $D$ . For  $\infty$ -categories a natural transformation takes objects to morphisms, morphisms to diagrams of shape  $\Delta^1 \times \Delta^1$  and generally an  $n$ -simplex to a diagram of shape  $\Delta^n \times \Delta^1$ .

**Theorem 1.0.2 (Pointwise criterion for natural isomorphism).** — *Let  $f, g : C \rightarrow D$  be functors of  $\infty$ -categories and  $T : f \rightarrow g$  be a natural transformation.  $T$  is a natural isomorphism if and only if for all objects  $x$  in  $C$ ,  $T(\{x\} \times \Delta^1)$  is an isomorphism in  $D$ .*

This is a consequence of Joyal's theorem.

**Definition.** — Define  $\text{Cat}_\infty$  as follows:

- Objects are  $\infty$ -categories.
- Morphisms are functors.
- 2-simplices are diagrams

$$\begin{array}{ccc} & X_1 & \\ f \nearrow & & \searrow g \\ X_0 & \xrightarrow{h} & X_2 \end{array}$$

and a natural isomorphism  $T : g \circ f \xrightarrow{\sim} h$ .

- 3-simplices and higher: copy the data of  $\text{Top}$  and replace  $[0, 1]^n$  by  $(\Delta^1)^n$ .

This is similar to  $\text{Top}$  and  $\text{Cat}_1$ .

**Definition.** — Define  $\text{Spc}$  same as above, except objects are  $\infty$ -groupoids.

In literature:  $\infty$ -groupoids, Kan complexes, spaces and anima are synonyms.

**Definition.** — A functor  $f : C \rightarrow D$  is called a **categorical equivalence** if there exists  $g : D \rightarrow C$  such that  $f \circ g \simeq \text{id}_D$  and  $g \circ f \simeq \text{id}_C$ .

**Theorem 1.0.3 (Fundamental Theorem of Category Theory).** — *A functor  $f : C \rightarrow D$  is a categorical equivalence if and only if it's essentially surjective and fully faithful.*

Note that we haven't defined essentially surjective or fully faithful. Let's pre-warm up first before we define them.

**Lemma 1.0.4.** — *Let  $X$  be a Kan complex.  $X$  is **contractible** (i.e., categorically equivalent to  $\Delta^0$ ) if and only if every lifting problem*

$$\begin{array}{ccc} \partial\Delta^n & \longrightarrow & X \\ \downarrow & \nearrow \text{dashed} & \downarrow \\ \Delta^n & \longrightarrow & \Delta^0 \end{array}$$

*admits a solution.*

Now we're warm enough to warm up, so let's do that. Let  $f : X \rightarrow Y$  be a map of Kan complexes. Suppose every lifting problem

$$\begin{array}{ccc} \partial\Delta^n & \longrightarrow & X \\ & \nearrow \text{dashed} & \downarrow f \\ \Delta^n & \longrightarrow & Y \end{array}$$

has a solution. Then  $f$  is a categorical equivalence (think: homotopy equivalence of topological spaces). But this condition is too strong for the converse. A simple counter-example is to take  $X$  contractible.

**Definition.** — Let  $f : C \rightarrow D$  be a functor of  $\infty$ -categories. Given

$$(1) \quad \begin{array}{ccc} \partial\Delta^n & \xrightarrow{r} & C \\ \downarrow & & \downarrow f \\ \Delta^n & \xrightarrow{s} & D \end{array}$$

we say it admits a **solution up to isomorphism** if

(i) there exists  $u : \Delta^n \rightarrow C$  such that

$$\begin{array}{ccc} \partial\Delta^n & \xrightarrow{r} & C \\ \downarrow & \nearrow u & \\ \Delta^n & & \end{array}$$

(ii)  $f \circ u : \Delta^n \rightarrow D$  is naturally isomorphic to  $s : \Delta^n \rightarrow D$  *relative* (of relative homotopy) to  $\partial\Delta^n$ .

**Definition.** — Let  $f : C \rightarrow D$  be a functor of  $\infty$ -categories.

- It's **essentially surjective** if every diagram (1) with  $n = 0$  admits a solution up to isomorphism.
- It's **full** if every diagram (1) with  $n = 1$  admits a solution up to isomorphism.
- It's **fully faithful** if every diagram (1) with  $n \geq 1$  admits a solution up to isomorphism.

So a functor of  $\infty$ -categories is fully faithful and essentially surjective if all (1) admit a solution up to isomorphism.

**Remark.** — These definitions of fully and full faithful are *nonstandard*.

Now the Fundamental Theorem makes sense.

*Proof idea.* The forward direction is easy. Conversely, we factor through

$$C \longrightarrow C^{\text{enhanced}} \longrightarrow D$$

where an  $n$ -simplex in  $C^{\text{enhanced}}$  is the data of

- $n$ -simplex in  $C$ ,
- a diagram of shape  $\Delta^n \times \Delta^1$  in  $D$  satisfying some conditions.

The inverses of the intermediate maps are easy to construct. □

What is missing so far is *mapping spaces*. Given objects  $X, Y$  in an  $\infty$ -category  $C$  we expect to find a space (Kan complex)  $\text{map}_C(X, Y)$  such that the objects of  $\text{map}_C(X, Y)$  are morphisms  $X \rightarrow Y$  and it should extend to a functor

$$\text{map}_C : C^{\text{op}} \times C \longrightarrow \text{Spc}.$$

For 1-categories this is usually called  $\text{Hom}$  or  $\text{Mor}$ . Lurie uses  $\text{Hom}$  for a non-functorial, but easier, version of  $\text{map}$ .

Here is one non-functorial approach to mapping spaces. Let  $C^{\Delta^1}$  be the simplicial set such that  $(C^{\Delta^1})_k$  is the set of maps  $\Delta^1 \times \Delta^k \rightarrow C$ . By restricting to  $\{0\} \times \Delta^k$  and  $\{1\} \times \Delta^k$  we get a map

$C^{\Delta^1} \rightarrow C \times C$ . Define  $\text{map}_C(X, Y)$  as the fiber product (of simplicial sets)

$$\begin{array}{ccc} \text{map}_C(X, Y) & \longrightarrow & C^{\Delta^1} \\ \downarrow & & \downarrow \\ \Delta^0 & \xrightarrow{(x, y)} & C \times C. \end{array}$$

**Theorem 1.0.4.** — *Let  $f : C \rightarrow D$  be a functor of  $\infty$ -categories. Then  $f$  is fully faithful if and only if for all objects  $X, Y$ , the induced map*

$$\text{map}_C(X, Y) \longrightarrow \text{map}_D(f(x), f(y))$$

*is a categorical equivalence of Kan complexes.*

This theorem is actually the usual definition in the literature.

Somewhere along the way:

**Theorem 1.0.5 (Whitehead's Theorem).** — *A map  $f : X \rightarrow Y$  of Kan complexes is a categorical equivalence if and only if*

$$\pi_n(X, x_0) \longrightarrow \pi_n(Y, f(x_0))$$

*are bijections for all  $n$  and all  $x_0$ .*

Lecture 3

A monoidal category in ordinary category theory consists of:

- A category  $C$ .
- A functor  $\otimes : C \times C \rightarrow C$ .
- An object  $\mathbb{1} \in C$ .
- 3 natural transformations: the associator, left and right unitors.

We ask them to satisfy 3 axioms:

- Triangle axioms (they say  $\mathbb{1} \otimes x = x = x \otimes \mathbb{1}$ ).
- Pentagon axiom (various ways to group 4 objects).

Mac Lane's Coherence Theorem tells us that every "reasonable" diagram made from the 3 natural transformations commutes.

Let's try to mimic this for  $\infty$ -categories. The naive approach is to start with:

- an  $\infty$ -category  $C$ ;
- a functor  $\otimes : C \times C \rightarrow C$ ;
- an object  $\mathbb{1} : \Delta^0 \rightarrow C$ ;
- an associator

$$\begin{array}{ccc} C \times C \times C & \xrightarrow{\text{id} \times \otimes} & C \times C \\ \downarrow \otimes \times \text{id} & \searrow \otimes & \downarrow \otimes \\ C \times C & \xrightarrow{\otimes} & C \end{array}$$

a diagram of shape  $\Delta^1 \times \Delta^1$  in  $\text{Cat}_\infty$ ;

- a left unitor

$$\begin{array}{ccc} \Delta^0 \times C & \xrightarrow{\mathbb{1} \times \text{id}} & C \times C \\ \searrow \sim & & \swarrow \otimes \\ & C & \end{array}$$

a 2-simplex in  $\text{Cat}_\infty$  and similarly a right unitor;

and ask it to satisfy

- the triangle identity

$$\begin{array}{ccccc} C \times \Delta^0 \times C & & & & \\ \text{id} \times \mathbb{1} \times \text{id} \downarrow & \searrow & \searrow & \searrow & \\ C \times C \times C & \xrightarrow{\quad} & C \times C & \xrightarrow{\quad} & C \\ & \searrow & \searrow & \searrow & \\ & C \times C & \xrightarrow{\quad} & C & \end{array}$$

two 3-simplices attached along a face.

We model these diagrams with totally ordered finite sets:

- Associator

- Left unitor

- Triangle identity

The data for the naive approach is modeled by

$$N \left( \left( \begin{array}{c} \text{nonempty, finite, totally ordered} \\ \text{sets of size } \leq 4 \end{array} \right)^{\text{op}} \right) \longrightarrow \text{Cat}_{\infty}$$

We are still missing the pentagon axiom and Mac Lane's Coherence Theorem.

**Definition.** — Let  $\mathcal{C}$  be an  $\infty$ -category. A **monoidal structure** on  $\mathcal{C}$  is a functor  $F : N(\Delta^{\text{op}}) \rightarrow \text{Cat}_{\infty}$  such that

- 1)  $F([1]) = \mathcal{C}$ ,
- 2) for all  $n$

$$[n] \leftarrow \{0, 1\}, \{1, 2\}, \dots, \{n-1, n\}$$

induces

$$F([n]) \longrightarrow \mathcal{C} \times \mathcal{C} \times \dots \times \mathcal{C} = \mathcal{C}^n$$

which we require to be an equivalence of categories.

Note that  $F([0]) \xrightarrow{\sim} \Delta^0$ . The idea is that the pentagon axiom and all “higher coherences” are encoded in  $\Delta^{\text{op}}$ .

The problem with this definition is unusable. Actually writing down a functor  $N(\Delta^{\text{op}}) \rightarrow \text{Cat}_{\infty}$  is too complicated. What do we do? Lurie will rescue us.

Let's warm up. Suppose you have a  $\Lambda_0^2$  horn

so we are asking: given

when does a solution exist? It exists if  $f$  has a right inverse.

**Definition.** — Let  $p : C \rightarrow D$  be a functor of  $\infty$ -categories,  $f : x \rightarrow y$  be a morphism in  $C$ . We say  $f$  is  *$p$ -cocartesian* if

$$\begin{array}{ccccc} \{0, 1\} = \Delta^1 & \xrightarrow{\quad} & \Lambda_0^n & \xrightarrow{\quad} & C \\ & & \downarrow & \nearrow & \downarrow p \\ & & \Delta^n & \xrightarrow{\quad} & D \end{array}$$

$f$  (curved arrow from  $\Delta^1$  to  $C$ )

has a solution.

**Definition.** —  $p : C \rightarrow D$  is called a **cocartesian fibration** if lifting problems

$$\begin{array}{ccc} \Lambda_j^n & \xrightarrow{r} & C \\ \downarrow & \nearrow & \downarrow p \\ \Delta^n & \xrightarrow{\quad} & D \end{array}$$

have a solution when

- (1)  $0 < j < n$ ,
- (2)  $j = 0$  and  $n \geq 2$  if  $r$  sends  $\{0, 1\}$  to a  $p$ -cocartesian edge (this is actually automatic),
- (3)  $j = 0, n = 1$ ; in this case we also *require* the solution  $u : \Delta^1 \rightarrow C$  to be a  $p$ -cocartesian edge.

The idea is that a cocartesian fibration  $p : C \rightarrow D$  should be thought of as a “functorial family of  $\infty$ -categories indexed by  $D$ ”. More precisely:

- For each object  $x$  in  $D$  let  $C_x = \{x\} \times_D C$ . This is an  $\infty$ -category.
- For each edge  $\gamma : x \rightarrow y$  in  $D$  and each  $n$ -simplex  $\sigma : \Delta^n \rightarrow C_x$  we can construct a map that under

$$\tilde{\sigma} : \Delta^n \times \Delta^1 \longrightarrow C$$

sends  $\{j\} \times \Delta^1$  to a  $p$ -cocartesian edge.

- Moreover, we get a *functor*

$$\begin{array}{ccc} C_x & \longrightarrow & C_y \\ \sigma & \longmapsto & \tilde{\sigma}_{\Delta^n \times \{1\}} \end{array}$$

(this is slightly sloppy).

The definition is precisely set up so you can carry this out. Let’s keep going:

- A 2-simplex in  $D$  gives a 2-simplex in  $\text{Cat}_\infty$

$$\begin{array}{ccc} & & C_y \\ & \nearrow & \downarrow \\ C_x & & C_z \end{array}$$

**Theorem 1.0.6 (Straightening-Unstraightening Theorem).** — *There is an equivalence of  $\infty$ -categories*

$$\text{Cocat}(D) \xrightarrow{\sim} \text{Fun}(D, \text{Cat}_\infty)$$

between the  $\infty$ -category of cocartesian fibrations over  $D$  and the  $\infty$ -category of functors  $D \rightarrow \text{Cat}_\infty$ . The forward map is called **straightening** and the inverse is called **unstraightening**.

The left hand side is easier for humans:

- Writing down a functor  $D \rightarrow \text{Cat}_\infty$  involves making millions of choices and checking that they’re compatible.
- Writing down a cocartesian fibration is *easier*: you write down *all* possible choices and don’t bother with compatibility.

**Definition.** — Let  $C$  be an  $\infty$ -category. A **monoidal structure** on  $C$  is a cocartesian fibration

$$C^{\otimes} \longrightarrow N(\Delta^{\text{op}})$$

such that

$$\begin{aligned} C_{[1]}^{\otimes} &= C \\ C_{[n]}^{\otimes} &\xrightarrow{\sim} C_{\{0,1\}}^{\otimes} \times C_{\{1,2\}}^{\otimes} \times \cdots \times C_{\{n-1,n\}}^{\otimes}. \end{aligned}$$

Let's go back to mapping spaces. We want a functor

$$\begin{aligned} C^{\text{op}} \times C &\longrightarrow \text{Spc} \subset \text{Cat}_{\infty} \\ (x, y) &\longmapsto \text{map}_C(x, y). \end{aligned}$$

This is impossible for humans.

Let's introduce the **twisted arrow category**  $\text{Tw}(C)$  for an  $\infty$ -category  $C$ . We define

$$\text{Tw}(C)_k = \{ \text{maps } N(k' < (k-1)' < \cdots < 1' < 0' < 0 < 1 < \cdots < k) \longrightarrow C \}.$$

Of course that poset is isomorphic to  $\Delta^{2k+1}$  but we want it to have this notation. We make the unprimed indices correspond to  $C$  and the primed indices to correspond to  $C^{\text{op}}$ , so we get a map

$$\text{Tw}(C) \longrightarrow C^{\text{op}} \times C.$$

**Lemma 1.0.5.** — *This is a cocartesian fibration whose fibers are Kan complexes.*

So by Straightening-Unstraightening we get a functor

$$\text{map}_C : C^{\text{op}} \times C \longrightarrow \text{Spc} \subset \text{Cat}_{\infty}.$$

By adjunction (1-categorical), we get

$$h : C \longrightarrow \text{Fun}(C^{\text{op}} \longrightarrow \text{Spc}).$$

**Theorem 1.0.7 ( $\infty$ -categorical Yoneda's Lemma).** —  *$h$  is fully faithful.*

**Remark.** — Straightening-Unstraightening gives you a framework for generalizing 1-categorical notions to  $\infty$ -categories. Some themes for going between ordinary and  $\infty$ -categories:

1-categories	$\infty$ -categories
Sets	Spaces
existence and uniqueness	existence for $\partial\Delta^n \rightarrow \Delta^n$ and $\forall n$ uniqueness up to a contractible Kan complex

**1.1. Pullbacks** In an ordinary category

$$\begin{array}{ccccc} X & & & & \\ & \searrow & & \searrow & \\ & & L & \longrightarrow & A \\ & \searrow & \downarrow & & \downarrow \\ & & A' & \longrightarrow & B \end{array}$$

$L$  is the pullback of

$$\begin{array}{ccc} & A & \\ & \downarrow & \\ A' & \longrightarrow & B \end{array}$$

if given solid arrows there exists a unique dashed arrow.

Now for the  $\infty$ -categorical version we need auxiliary simplicial sets

$$P_n = N(??)$$

(I need to think about how to write this, it's a poset  $0 < \cdots < n+1$  with a square made at the end with  $a, a', b$ .) The standard notation for this simplicial set is  $\Delta^{n+1} * \Lambda_2^2$ , where  $*$  stands for the join

operation, which we won't define. Also define  $P_n^0$  to be the subsimplicial set of  $P_n$  where we take chains that omit one of  $0, 1, \dots, n+1$ . The standard notation is

$$\Delta^n * \Lambda_2^2 \coprod_{\partial \Delta^n * \Lambda_2^2} \partial \Delta^n * (\Delta^1 \times \Delta^1)$$

it also might be  $\partial \Delta^{n+1} * \Lambda_2^2$  but Pramod wasn't sure.

(Pictures of  $P_i$  and  $P_i^0$ .)
